BLACK HOLE ORBITS IN SUPERGRAVITY

K. S. Stelle

Duality symmetries are used to organise symmetry orbits of supergravity black-hole solutions and to display their relation to extremal (i.e., BPS) solutions at the limits of such orbits. An important technique for this analysis uses a timelike dimensional reduction and exchanges the stationary black-hole problem for a nonlinear sigma-model problem. Families of BPS solutions are characterized by nilpotent orbits under the duality symmetries, based upon a tri-graded or penta-graded decomposition of the corresponding duality group algebra.

Keywords: supergravity, black holes, duality symmetries, sigma-model.

The study of families of black-hole solutions is of considerable current interest because it touches upon many important issues in theoretical physics. For example, the classification of BPS and non-BPS black holes forms part of a more general study of branes in supergravity and superstring theory. Branes and their intersections, as well as their worldvolume modes and attached string modes, are also key elements in phenomenological approaches to the marriage of string theory with particle physics phenomenology. The related study of nonsingular and horizon-free BPS gravitational solutions is also central to the "fuzzball" proposal of BPS solutions as candidate black-hole quantum microstates. Brane solutions are also the basis for a number of early-universe cosmology candidates.

The search for supergravity solutions with assumed Killing symmetries can be recast as a Kaluza-Klein problem [1–3]. To see this, consider a 4D theory with a nonlinear bosonic symmetry \( G_4 \) (e.g., the "duality" symmetry \( E_7 \) for maximal \( N = 8 \) supergravity). Scalar fields take their values in a target space \( \Phi_4 = G_4/H_4 \), where \( H_4 \) is the corresponding linearly realized subgroup, generally the maximal compact subgroup of \( G_4 \) (e.g., \( SU(8) \) \( \subset \) \( E_7 \) for \( N = 8 \) \( S\Gamma \)). The search will be constrained by the following considerations:

- We assume that a solution spacetime is asymptotically flat or asymptotically Taub-NUT and that there is a radial function \( r \) which is divergent in the asymptotic region, \( g^{\mu \nu} \partial_\mu r \partial_\nu r \sim 1 + \mathcal{O}(r^{-1}) \).
- Searching for stationary solutions amounts to assuming that a solution possesses a timelike Killing vector field \( \kappa_\mu(x) \). Lie derivatives with respect to \( \kappa_\mu \) are assumed to vanish on all fields. The Killing vector \( \kappa_\mu \) will be assumed to have \( W := -g_{\mu \nu} \kappa^\nu \kappa^\mu \sim 1 + \mathcal{O}(r^{-1}) \).
- We also assume asymptotic hypersurface orthogonality, i.e., \( \kappa^\nu (\partial_\mu \kappa_\nu - \partial_\nu \kappa_\mu) \sim \mathcal{O}(r^{-2}) \). In any vielbein frame, the curvature will then fall off as \( R_{abcd} \sim \mathcal{O}(r^{-3}) \).

The 3D theory obtained after dimensional reduction with respect to a timelike Killing vector \( \kappa_\mu \) will have an Abelian principal bundle structure, with a metric

\[
    ds^2 = -W(dt + B_\nu dx^\nu)^2 + W^{-1} \gamma_{ij} dx^i dx^j, \tag{1}
\]

where \( t \) is a coordinate adapted to the timelike Killing vector \( \kappa_\mu \) and \( \gamma_{ij} \) is the metric on the 3-dimensional hypersurface \( M_3 \) at constant \( t \). If the 4D theory also has Abelian vector fields \( A_\mu \), they similarly reduce to 3D as

\[
    4\sqrt{\frac{4\pi G}{M}} A_\mu dx^\mu = U(dt + B_\nu dx^\nu) + A_\nu dx^\nu. \tag{2}
\]

The timelike reduced 3D theory will have a \( G/H^* \) coset space structure similar to the \( G/H \) coset space structure of a 3D theory reduced with a spacelike Killing vector. Thus, for the spacelike reduction of maximal supergravity down to 3D, one obtains an \( E_8/\text{SO}(16) \) theory from the sequence of dimensional reductions descending from \( D = 11 \) [4]. The resulting 3D theory has this exceptional symmetry because 3D Abelian vector fields can be dualized to scalars; this also happens for the analogous theory subjected to a timelike reduction to 3D. The resulting 3D theory contains 3D gravity coupled to a \( G/H^* \) nonlinear sigma model.

Although the numerator group \( G \) for a timelike reduction is the same as that obtained in a spacelike reduction, the divisor group \( H^* \) for a timelike reduction is a noncompact form of the spacelike divisor group \( H \) [2]. A consequence of this \( H \to H^* \) change and the dualization of vectors is the appearance of negative-sign kinetic terms for some 3D scalars.

---

1An expanded version of this note will appear in the Festschrift in honor of the 75th birthday of Professor Andrei Alekseevich Slavnov.
Consequently, maximal supergravity, after a timelike reduction to 3D and the subsequent dualization of 29 vectors to scalars, has a bosonic sector containing 3D gravity coupled to a $E_8/SO^\ast(16)$ nonlinear sigma model with 128 scalar fields. As a consequence of the timelike dimensional reduction and vector dualizations, however, the scalars do not all have the same signs for their “kinetic” terms:

- There are 72 positive-sign scalars: 70 descending directly from the 4D theory, one emerging from the 4D metric and one more coming from the $D = 4 \to D = 3$ Kaluza-Klein vector, subsequently dualized to a scalar.
- There are 56 negative-sign scalars: 28 descending directly from the time components of the 28 4D vectors, and another 28 emerging from the 3D vectors. These 28 4D vectors obtained from spatial components of the 28 4D vectors, becoming then negative-sign scalar after dualization.

The sigma-model structure of this timelike reduced maximal theory is $E_8/SO^\ast(16)$. The $SO^\ast(16)$ divisor group is not an $SO(p,q)$ group defined via preservation of an indefinite metric. Instead it is constructed starting from the SO(16) Clifford algebra $\{1^i,1^J\} = 2\delta^{ij}$ and then by forming the complex $U(8)$-covariant oscillators $a_i \equiv 1/2(\Gamma_{2i-1} + i\Gamma_{2i})$ and $a^i \equiv (a_i)^\dagger = 1/2(\Gamma_{2i-1} - i\Gamma_{2i})$. These satisfy the standard fermi oscillator annihilation/creation anticommutation relations

$$\{a_i, a_j\} = \{a^i, a^j\} = 0 \quad, \quad \{a_i, a^j\} = \delta_i^j.$$  

The 120 $SO^\ast(16)$ generators are then formed from the 64 hermitian $U(8)$ generators $a_i^J$ plus the $2 \times 28 = 56$ antihermitian combinations of $a_{ij} \pm a^{ij}$. Under $SO^\ast(16)$, the vector representation and the antichiral spinor are pseudo-real, while the 128-dimensional chiral spinor representation is real. This is the representation under which the 72+56 scalar fields transform in the $E_8/SO^\ast(16)$ sigma model.

The 3D classification of extended supergravity stationary solutions via timelike reduction generalizes the 3D supergravity systems obtained from spacelike reduction [5]. This also connects with $N = 2$ models with coupled vectors [6] and $N = 4$ models with vectors, where solutions have also been generated using duality symmetries [7,8].

The process of timelike dimensional reduction down to 3 dimensions together with dualization of all form-fields to scalars produces an Euclidean gravity theory coupled to a $G/H^\ast$ nonlinear sigma model, $I_\sigma = \int d^3x \sqrt{\gamma}(R(\gamma) - \frac{1}{2}G_{AB}(\phi)\partial_\gamma^A\partial_\gamma^BG_{ij}^\gamma)$, where $G_{AB}(\phi)$ is the $G/H^\ast$ sigma-model target-space metric and $\gamma_{ij}$ is the 3D metric. Varying this action produces the 3D field equations

$$\nabla_i(\sqrt{\gamma}G_{AB}(\phi)\partial_\gamma^A\partial_\gamma^B) = 0$$  

and

$$R_{ij}(\gamma) = \frac{1}{2}G_{AB}(\phi)\partial_\gamma^A\partial_\gamma^B.$$  

where $\nabla_i$ is a doubly covariant derivative (for the 3D space $M_3$ and for the $G/H^\ast$ target space).

Now one can make the simplifying assumption that $\phi^A(\gamma) = \phi^A(\sigma(x))$, with a single intermediate map $\sigma(x)$. Subject to this assumption, the field equations become

$$\nabla^2\sigma \frac{d\phi^A}{d\sigma} + \gamma^{ij}\partial_i\sigma\partial_j\sigma[\frac{\partial^2\phi^A}{d\sigma^2} + \Gamma_{BC}^A(G)\frac{d\phi^B}{d\sigma}\frac{d\phi^C}{d\sigma}] = 0,$$

$$R_{ij} = \left(\frac{1}{2}G_{AB}(\phi)\frac{d\phi^A}{d\sigma}\frac{d\phi^B}{d\sigma}\right)\partial_i\phi^A\partial_j\phi^B.$$  

Now one uses the gravitational Bianchi identity $\nabla^i(R_{ij} - \frac{1}{2}\gamma_{ij}R) \equiv 0$ to obtain $\frac{d^2\phi^A}{d\sigma^2} + \Gamma_{BC}^A(G)\frac{d\phi^B}{d\sigma}\frac{d\phi^C}{d\sigma} = 0$ and $\frac{d}{d\sigma} \left(\frac{1}{2}G_{AB}(\phi)\frac{d\phi^A}{d\sigma}\frac{d\phi^B}{d\sigma}\right) = 0$.

The first equation (7) above implies that $\sigma(x)$ is a harmonic map from the 3D space $M_3$ into a curve $\phi^A(\gamma)$ in the $G/H^\ast$ target space. The second equation (8) implies that $\phi^A(\gamma)$ is a geodesic in $G/H^\ast$. The third equation (9) implies that $\gamma$ is an affine parameter. The decomposition of $\phi : M_3 \to G/H^\ast$ into a harmonic map $\gamma : M_3 \to \mathbb{R}$ and a geodesic $\phi : \mathbb{R} \to G/H^\ast$ is in accordance with a general theorem on harmonic maps [9] according to which the composition of a harmonic map with a totally geodesic one is again harmonic. Such factorization into geodesic and harmonic maps is also characteristic of general higher-dimensional $p$-brane supergravity solutions [1,3].

Here is a sketch of the map composition:

Now define the Komar two-form $K \equiv \partial_\mu K_\nu dx^\mu \wedge dx^\nu$. This is invariant under the action of the timelike isometry and, by the asymptotic hypersurface orthogonality assumption, is asymptotically horizontal. This condition is equivalent to the requirement that the scalar field $\beta$ dual to the Kaluza-Klein vector arising out of the 4D metric must vanish like $O(r^{-1})$ as $r \to \infty$. In this case, one can define the Komar mass and NUT
charge by (where $s^*$ indicates a pull-back to a section) \[ n \equiv \frac{1}{8\pi} K \int_{\partial M_3} s^* K. \quad (10) \]

The Maxwell field also defines charges. Using the Maxwell field equation $d \mathcal{F} = 0$, where $\mathcal{F} \equiv \delta \mathcal{L} / \delta F$ is a linear combination of the two-form field strengths $F$ depending on the 4D scalar fields, and using the Bianchi identity $dF = 0$, one obtains conserved electric and magnetic charges:

\[ q \equiv \frac{1}{2\pi} K \int_{\partial M_3} s^* \mathcal{F}, \quad p \equiv \frac{1}{8\pi} K \int_{\partial M_3} s^* F. \quad (11) \]

Now consider these charges from the three-dimensional point of view in order to clarify their transformation properties under the 3D duality group $G$. The three-dimensional theory is described in terms of a coect representative $\mathcal{V} \in G/H^\ast$. The Maurer-Cartan form $\mathcal{V}^{-1} d\mathcal{V} = Q + P$, $Q \equiv Q_\mu dx^\mu \in h^\ast$, $P \equiv P_\mu dx^\mu \in g \oplus h^\ast$. \[ \gamma h \oplus e \oplus \varphi \mathfrak{f} = \begin{pmatrix} \gamma & e \\ -e & \varphi \end{pmatrix} \quad (16) \]

and its Lie algebra is $[h, e] = 2e$, $[h, f] = -2f$, $[e, f] = h$.

Accordingly, in reducing from 4D to 3D a supergravity theory with 4D symmetry group $G_4$, with corresponding Lie algebra $\mathfrak{g}_4$ and with vectors transforming in the $l_4$ representation of $\mathfrak{g}_4$, one obtains a $p$-graded structure for the 3D Lie algebra $\mathfrak{g}$ with the Ehlers group $\mathfrak{h}$ now acting as the grading generator $1^{(0)}$:

\[ \mathfrak{g} \simeq 1^{(-2)} \oplus l_4^{(-1)} \oplus (1 \oplus \mathfrak{g}_4^{(0)} \oplus l_4^{(1)} \oplus 1^{(2)}). \quad (17) \]

For example, in 3D maximal supergravity one obtains in this way $\mathfrak{e}_{0,8}$:

\[ \mathfrak{e}_{0,8} \simeq 1^{(-2)} \oplus 56^{(-1)} \oplus (1 \oplus \mathfrak{e}_{7,7}^{(0)} \oplus 56^{(+1)} \oplus 1^{(2)} \quad (248 \text{ generators}). \quad (18) \]

Now apply this to the decomposition of the coset-space structure for the 3D scalar fields and the charge matrix $\mathcal{C}$. In 4D, the scalars are associated to the coect generators $\mathfrak{h}_4 \oplus \mathfrak{b}_4$, where $\mathfrak{b}_4$ is the Lie algebra of the 4D divisor group $H_4$. The representation carried by the 4D electric and magnetic charges $q$ and $p$ is $l_4$. Then the 3D scalars and the charge matrix $\mathcal{C}$ can be decomposed into three irreducible representations with respect to $\mathfrak{so}(2) \oplus \mathfrak{b}_4$ according to

\[ \mathfrak{g} \oplus h^\ast \cong (\mathfrak{sl}(2, \mathbb{R}) \oplus \mathfrak{so}(2)) \oplus l_4 \oplus (K \mathfrak{g}_4 \oplus \mathfrak{b}_4). \quad (19) \]
The metric induced by the \( g \) algebra’s Cartan-Killing metric on this coset space is positive definite for the first and last terms, but is negative definite for \( t_i \). One associates the \( \mathfrak{sl}(2, \mathbb{R}) \oplus \mathfrak{so}(2) \) components with the Konar mass and the Konar NUT charge, while the \( t_i \) components are associated with the electromagnetic charges. The remaining \( a_0 \oplus h_1 \) charges belong to the Noether current of the 4D theory.

Breitenlohner, Gibbons and Maison \[2\] proved that if \( G \) is simple, all the non-extremal single-black-hole solutions of a given theory lie on the \( H^* \) orbit of a Kerr solution. Moreover, all \textit{static} solutions regular outside the horizon with a charge matrix satisfying \( \text{Tr} \mathcal{C}^2 > 0 \) lie on the \( H^* \)-orbit of a Schwarzschild solution. (Turning on and off angular momentum requires consideration of the \( D = 2 \) duality group generalizing the Geroch \( A_1^1 \) group.)

Using Weyl coordinates, where the 4D metric takes the form
\[
\begin{align*}
    d\tau^2 &= f(x, \rho)^{-1}(c^2 k(x, \rho)(d\rho^2 + dp^2) + \rho^2 d\phi^2) + f(x, \rho)(dt + A(x, \rho) d\phi)^2, \\
    &\quad \text{where } x = \text{diag}(2, 1, 0, -1, -2),
\end{align*}
\]
the coset representative \( V \) associated to the Schwarzschild solution with mass \( m \) can be written in terms of the non-compact generator \( h \) of the Ehlers \( \mathfrak{sl}(2, \mathbb{R}) \) only, i.e.
\[
    V = \exp \left( \frac{1}{2} \ln \frac{r - m}{r + m} \right) h \, \mathcal{C} = mh.
\]

For the maximal \( N = 8 \) theory with symmetry \( \mathfrak{E}_{8(8)} \) (and also for the exceptional ‘magic’ \( N = 2 \) supergravity \[12\] with symmetry \( \mathfrak{E}_{8(-24)} \), one has \( h = \text{diag}(2, 1, 0, -1, -2) \), so
\[
    h^2 = 5h^3 - 4h
\]
Consequently, the charge matrix \( \mathcal{C} \) satisfies in all cases the characteristic equation
\[
    \mathcal{C}^5 = 5c^2\mathcal{C}^3 - 4c^4\mathcal{C},
\]
where \( c^2 = -\frac{1}{\pi \epsilon^2} \text{Tr} \mathcal{C}^2 \) is the \textit{extremality parameter} (\( c^2 = 0 \) for extremal static solutions; \( c^2 = m^2 \) for Schwarzschild). Moreover, for all but the two exceptional \( \mathfrak{E}_8 \) cases, a stronger constraint is actually satisfied by the charge matrix \( \mathcal{C} \):
\[
    \mathcal{C}^3 = c^2 \mathcal{C}.
\]
The characteristic equation selects acceptable orbits of solutions, i.e. orbits not exclusively containing solutions with naked singularities. It determines \( \mathcal{C} \) in terms of the mass and NUT charge and the 4D electromagnetic charges.

The parameter \( c^2 \) is the same as the (target space velocity)\(^2\) of the harmonic-map discussion: \( c^2 = u^2 \). The Maxwell-Einstein theory is the simplest example with an indefinite-signature sigma-model metric, for the scalar-field target space \( G/H^* = \text{SU}(2,1)/\text{SU}(1,1) \times \text{U}(1) \). The Maxwell-Einstein charge matrix is
\[
    \mathcal{C}_{\text{ME}} = \begin{pmatrix}
    m & n & -z/\sqrt{2} \\
    n & -m & iz/\sqrt{2} \\
    z/\sqrt{2} & iz/\sqrt{2} & 0
    \end{pmatrix} \in \mathfrak{su}(2,2) \oplus \mathfrak{u}(1,1)
\]
where \( z = q + ip \) is the complex electromagnetic charge. The Maxwell-Einstein extremality parameter is \( c^2 = m^2 + n^2 - z z \). Solutions fall into three categories: \( c^2 > 0 \) nonextremal, \( c^2 = 0 \) extremal and \( c^2 < 0 \) hyperextremal. The hyperextremal solutions have naked singularities, while the nonextremal and extremal solutions have their singularities cloaked by horizons.

Extremal solutions have \( c^2 = 0 \), implying that the charge matrix \( \mathcal{C} \) becomes \textit{nilpotent}: \( \mathcal{C}^5 = 0 \) in the \( \mathfrak{E}_8 \) cases and \( \mathcal{C}^3 = 0 \) otherwise.

For \( N \) extended supergravity theories, one finds \( H^* \cong \text{Spin}^+(2N) \times H_0 \) and the charge matrix \( \mathcal{C} \) transforms as a Weyl spinor of \( \text{Spin}^+(2N) \) also valued in a representation of \( B_0 \) (where \( B_0 \) acts on the matter content of reducible \( N = 4 \) theories). As in the \( SO^+(16) \) case considered earlier, one defines the \( \text{Spin}^+(2N) \) fermionic oscillators
\[
    a_i := \frac{1}{2}(\Gamma_{2i-1} + i\Gamma_{2i}),
\]
\[
    a^i \equiv (a_i)^\dagger = \frac{1}{2}(\Gamma_{2i-1} - i\Gamma_{2i})
\]
for \( i, j, \ldots = 1, \ldots, N \). These obey standard fermionic annihilation & creation anticommutation relations. Using this annihilation/creation oscillator basis, the charge matrix \( \mathcal{C} \) can be represented as a state (where \( a_i \langle 0 | = 0 \))
\[
    |\mathcal{C}\rangle \equiv (K W + Z_i a^i a^i + \Sigma_{ijkl} a^i a^j a^k a^l + \cdots ) K |0\rangle.
\]

From the requirement that the dilatino fields be left invariant under the unbroken supersymmetry of a BPS solution, one derives a ‘Dirac equation’ for the charge state vector,
\[
    \left( \epsilon^i_+ a_i + \Omega_{ab} \epsilon^a_+ a^b \right) |\mathcal{C}\rangle = 0
\]
where \( \left( \epsilon^i_+ , \epsilon^i_+ \right) \) is the asymptotic (for \( r \to \infty \)) value of the Killing spinor and \( \Omega_{ab} \) is symplectic form on \( \mathbb{C}^{2n} \), in cases with \( n/N \) preserved supersymmetry.

Note that \( c^2 = 0 \iff \langle \mathcal{C}|\mathcal{C}\rangle = 0 \) is a weaker condition than the supersymmetry Dirac equation. Extremal and BPS are not always synonymous conditions, although they coincide for \( N \leq 5 \) pure supergravities. They are not synonymous for \( N = 6 \& 8 \) or for theories with vector matter coupling.
Earlier analysis of the orbits of the 4D symmetry groups \( G_4 \) [13] heavily used the Iwasawa decomposition \[ g = u(g, z) \exp \left( \ln \lambda(g, z) z \right) b(g, z) \] (29) with \( u(g, z) \in H_4 \) and \( b(g, z) \in B_4 \), where \( B_4 \subset G_4 \) is the parabolic subgroup that leaves the charges \( Z \) invariant up to a multiplicative factor \( \lambda(g, z) \). This multiplicative factor can be compensated for by ‘trombone’ transformations combining Weyl scalings with compensating dilational coordinate transformations, leading to a formulation of active symmetry transformations that map solutions into other solutions with unchanged asymptotic values of the spacetime metric and scalar fields.

The 4D ‘trombone’ transformation finds a natural home in the parabolic subgroup of the 3D duality group \( G \). The 3D structure is characterized by the fact that the Iwasawa decomposition breaks down for noncompact divisor groups \( H^\ast \).

The Iwasawa decomposition does, however work “almost everywhere” in the 3D solution space. The places where it fails are precisely the extremal suborbits of the duality group. There are \( G \) transformations which allow one to send \( c^2 \rightarrow 0 \), thus landing on an extremal (generally BPS) suborbit. However, one cannot then invert the map and return to a generic non-extremal solution from the extremal solution reached on a given \( G \) trajectory.

The above framework applies equally to multi-centered as to single-centered solutions [14, 15]. One may start from a general ansatz

\[ \mathcal{V}(x) = V_0 \exp(-\sum_n \mathcal{H}^n(x) \mathcal{C}_n) \] (30)

with Lie algebra elements \( \mathcal{C}_n \in g \ominus h^\ast \) and functions \( \mathcal{H}^n(x) \) to be determined by the equations of motion. Defining as above \( V^{-1} dV = Q + P \) and restricting \( P \) to depend linearly on the functions \( \mathcal{H}^n(x) \), one finds the requirement \( [K \mathcal{C}_m, \mathcal{C}_n \mathcal{C}_p] = 0 \). The Einstein and scalar equations of motion then reduce to

\[ R_{\mu \nu} - \frac{1}{2} g_{\mu \nu} R = \sum_{mn} \partial_\mu \mathcal{H}^m \partial_\nu \mathcal{H}^n \text{Tr} \mathcal{C}_m \mathcal{C}_n, \] (31)

\[ d * d \mathcal{H}^0 = 0. \] (32)

Restricting attention to solutions where the 3-space is flat then requires \( \text{Tr} \mathcal{C}_m \mathcal{C}_n = 0 \). The resulting system generalizes that found in [3]. Solving \( [K \mathcal{C}_m, \mathcal{C}_n \mathcal{C}_p] = 0 \) = \( \text{Tr} \mathcal{C}_m \mathcal{C}_n \) is now reduced to an algebraic problem amenable to the above nilpotent-orbit analysis: non-extremal and extremal stationary solutions can be formed from extremal single-hole constituents.

In summary, what has been developed here is a quite general framework for the analysis of stationary supergravity solutions using duality orbits. The Noether charge matrix \( \mathcal{C} \) satisfies a characteristic equation \( \mathcal{C}^3 = 5c^2 \mathcal{C}^3 - 4c^4 \mathcal{C} \) in the maximal \( E_8 \) cases and \( \mathcal{C}^3 = c^2 \mathcal{C} \) in the non-maximal cases, where \( c^2 \equiv 1 \text{Tr} \mathcal{H}^2 \) is the extremality parameter. Extremal solutions are characterized by \( c^2 = 0 \), and \( \mathcal{C} \) becomes nilpotent \((\mathcal{C}^3 = 0 \text{ or } \mathcal{C}^3 = 0)\) on the corresponding extremal suborbits. BPS solutions have a charge matrix \( \mathcal{C} \) satisfying an algebraic ‘supersymmetry Dirac equation’ which encodes the general properties of such solutions. This is a stronger condition than the \( c^2 = 0 \) extremality condition. The orbits of the 3D duality group \( G \) are not always acted upon transitively by \( G \). This is related to the failure of the Iwasawa decomposition for noncompact divisor groups \( H^\ast \).

The Iwasawa failure set corresponds to the extremal suborbits.

Black hole orbits in supergravity

ORBITY ČERNÝCH DÝR V SÚPERGRAVITACIÍ

Дуальные симметрии используются для построения симметричных орбит в решениях для чёрных дыр в супергравитации и для выявления их связи с внешними решениями (т.е. BPS) в пределе таких орбит. Используемый для данного анализа подход сводит задачу стационарной чёрной дыры к задаче вакуумной симметрии. Следствием BPS решений характеризуется низкотеппературными орбитаами дуальной симметрии.

Ключевые слова: супергравитация, чёрные дыры, симметрии дуальности, симма-модель.
